

OIL SPILL COUNTERMEASURE LOGISTICS STUDY

SUMMARY REPORT

TD 195 P4 0394 c.1 POLAR

ABSTRACT

The Summary Report is one of two major reports submitted as part of the Oil Spill Countermeasure Logistics Study of the Transportation Infrastructure. This is one of the projects commissioned by the Department of Fisheries and the Environment as part of the AMOPS program. A second Analysis Report also forms part of this project. The appendices to the project form the basis for the discussions in both the Summary Report and the Analysis Report and are included under separate cover.

The Summary Report provides tabulated listings of the various aspects of the transportation infrastructure for which information was collected. Much greater detail is contained in the appendix sheets. The study itself concerned a collection of data for the air system, marine system, land system and communities in the north.

The air system information includes tabulations of the characteristics of the available aircraft for use in the north in terms of their classification as heavy, medium or light transports or helicopters. Of importance also is the summary of the companies presently operating in the north and their types of licence. The report also includes a description of the air strips available for operations in the north and the contacts and sources from which the information was gathered. A section is also included on special technology and future developments for the air system and the marine and land systems.

The summary of the marine system includes tabulations of the available vessels which have had experience in the north, the government agencies and companies operating in the north, and a more detailed description of the ports and anchorages which would be available for use in the event of an oil spill. This includes the description of categories of ports and anchorages, selected sites, description of pollution control zones, their chart numbers, the degree of shelter and anchorage. As before, there are descriptions of the sources and contacts and special technology in future developments in the marine system.

The summary of land systems includes a description of the rail access to the north, the road access to the north, the possibility of use of air cushion vehicles and as before, sources and contacts and future developments. The summary of communities in the north describes the population, location and facility available.

The information included in this report and the Analysis report has been summarized by region within the Arctic. Five separate regions have been considered:

- Western Arctic
- · Fastern Arctic
- High Arctic
- Hudson Bay/Ungava/Foxe Basin
- Labrador Coast

This has been undertaken to provide a convenient basis for comparison of the various systems within a given area.

ACKNOWLEDGEMENTS

The authors would like to acknowledge the excellent cooperation received from Mr. K. Meikle and Mr. W. Logan as representatives of the Environmental Protection Service. Also without the cooperation and efforts of the staff of many governmental agencies, the railways, airlines and shipping companies surveyed in the study, our task would have been much more difficult. The Department of National Defence deserves special acknowledgement for their cooperation. In particular Captain Jordaan and Major Paukstaitis provided excellent material.

Figures 59, 60, 61, 62, 63 in the Analysis Report were reproduced with the permission of Northern Associates (Holdings) Ltd. who originally prepared the material under contract to the Ministry of Transport for a report entitled "Arctic Resources by Sea".

1.0 INTRODUCTION

This report is an executive summary of the data collection phase of the Oil Spill Countermeasure Logistics Study. Chapters 2, 3, 4 and 5 present summaries of the air systems, marine systems, land systems and communities respectively. The data have been collected from a wide variety of sources and recorded on forms developed specifically for this project. These data sheets are contained in an Appendix Report and represent the source for the following summaries.

For the purpose of this report the study area has been divided into the following five geographic regions as shown on Map 1.

- a) Western Arctic
- b) Eastern Arctic
- c) High Arctic
- d) Hudson Bay/Ungava/Foxe Basin
- e) Labrador Coast
- a) The Western Arctic is identified as that area lying west of an imaginary line running north-south through the centre of Somerset Island and the Boothia Peninsula and south of Melville Sound. This area encompasses all the settlements and ports on the western Arctic Coast (including Spence Bay) and on Banks Island, Victoria Island and King William Island.
- b) The Eastern Arctic in this instance, is predominantly eastern Baffin Island. The borders of this region are as follows: The Western boundary is the north-south line running from Barrow down the centre of Somerset Island and the Boothia Peninsula; the northern and eastern limits are Lancaster Sound and a line running down through Davis Strait. The southern limit is a line running from the Gulf of Boothia through the centre of Baffin Island easterly to its southern tip including Frobisher Bay.
- c) The High Arctic area is defined as that area lying north of an imaginary line connecting the Arctic Ocean to Baffin Bay, running through Lancaster Sound, Barrow Strait, Viscount Melville Sound and McClure Strait.
- d) The Hudson Bay/Ungava/Foxe Basin area includes all the ports and settlements surrounding the Foxe Basin, Hudson Bay, Hudson Strait and Ungava Bay as far east as Cape Chidley.
- e) The Labrador Coast includes all settlements on the Labrador Coast from Cape Chidley to 53°N latitude.

2.0 SUMMARY OF AIR SYSTEMS

The ability to transport men and equipment on short notice would depend primarily on the capacity of the air system composed of a fixed wing fleet and a rotary wing fleet. The fixed wing fleet available is composed of a variety of makes and models with varying configurations for carrying passengers and/or freight. The fleet can be divided conveniently into three classifications as follows:

- Heavy Transports
 - Aircraft capable of long range delivery of large loads at relatively high speeds. These aircraft would serve as the major transport from southern supply stations and would be capable of transporting some types of construction vehicles.
- · Medium Transports

Aircraft capable of a shorter range and delivery of smaller payloads. These craft would not be capable of transporting large construction equipment and would be used for more localized delivery.

- · Light Transports
 - Aircraft capable of short range transport to the operational sites. These aircraft would operate from shorter airstrips but would be only capable of transporting relatively small loads. They would serve a reconnaissance role as well.

Helicopters can also be defined as light, medium and heavy, but this classification pertains only to load capacity. The relatively slow ferrying speeds eliminate this mode as a long range delivery vehicle. The major benefit of helicopters relates to the small area required for landing and the flexibility with respect to size and shape of package which can be transported externally.

The airstrips in the north are not sophisticated in equipment or facilities for repair and accommodation. The life of many strips is limited by their purpose (exploration, DEW Line) or by their construction base (ice). The status of the airstrips described herein is highly dynamic and updating on a regular basis is essential.

Aircraft by themselves are not capable of operations in the Arctic. The environment and navigational procedures make experience in the area necessary for safe and efficient operations. The summary of companies familiar with the conditions and limitations is therefore essential.

2.1 AVAILABLE AIRCRAFT

The aircraft operating in the north are of many sizes and have varying operational capabilities. Table 1 summarizes the characteristics of these aircraft. The various classes of aircraft are grouped, heavy transports first; then medium transports; followed by the light transports. The file number refers to the inventory sheet reference to be included in the Appendix Report. Disposable Weight refers to the poundage available to carry payload and fuel. The runway requirements are for full aircraft operating under Canadian Transport Commission regulations. In actual operations, partial loads can easily be landed on shorter strips. The use of shorter strips is also facilitated by the low temperatures and altitude, two factors which increase air density and thus the lift capability of the wings.

2.1.1 Heavy Transports

There are five types of aircraft operating in the north which could be classified as "Heavy Transports": of these, some operate in freight or mixed passenger/freight configurations while others operate only in the freight configuration.

The Boeing 727 and 737 are jet aircraft capable of landing on gravel strips when specially equipped. They have a shorter range but high speed capability and are operated in mixed configurations.

The Hercules aircraft is the ideal mode for freight because of its large capacity and hatch dimensions combined with long range capability. It has also been used in experimental low altitude drops and is frequently used in the Arctic.

The Lockheed Electra and Douglas DC-6 are smaller aircraft but still perform a satisfactory function as heavy transports over a long range.

2.1.2. Medium Transports

There are five types of medium transports capable of carrying up to 13,500 lbs. for short range flights and up to 1,500 nautical miles with smaller loads. All are operational in the north, although the Buffalo is not available as a commercial craft, but is utilized by the Canadian Armed Forces.

2.1.3 Light Transports

Of the light aircraft only the Twin Otter is used extensively for freight or passenger transport. Its STOL characteristics and high reliability in cold weather make it ideal for application under operational conditions where only short airstrips are available, and maintenance capability is minimal.

2.1.4 Helicopters

Table 2 summarizes the characteristics of the helicopters identified in this project. The range of payloads is smaller and the difference between heavy and medium capacities less distinct with the exception of the Chinook which has a very heavy payload in comparison.

All helicopters normally have sling capabilities for external loads. This permits them to lift large objects including those with awkward shapes.

There are four heavy helicopters capable of transporting between 7,348 and 26,000 lbs. The Puma, the Chinook the Labrador/Voyageur and S61L are used for personnel and freight transport. There are four medium helicopters capable of transporting between 3,512 and 5,800 lbs. All are jet propelled and capable of freight transport internally.

There are six light helicopters capable of lifting between 500 and 2,700 lbs. Only the Bell series 47 are gasoline powered. They are small and are more suitable for use in reconnaissance, not freight transport.

2.2 COMPANIES OPERATING IN THE NORTH

2.2.1 Commercial Operations

The companies operating in the north can be classified according to the type of aircraft they are flying and the areas within which they operate.

Heavy transport is the province of the regional airlines, Northwest Territorial Airlines and the Canadian Armed Forces. Both medium and light transport are usually offered by the smaller firms. Table 3 shows the larger firms and the major equipment which they operate. There are also a large number of local operators who fly small craft which would not have a significant impact on any oil spill clean-up operations from a transport point of view.

The regional carriers operate throughout the north (in their own corridors) to the major centres. The smaller operators are more restricted (because of aircraft range and market conditions) and can be classified as to area of operation as in Table 4.

Helicopters are operated by fewer companies. Okanagan Helicopters is by far the biggest and most experienced operator as shown on Table 5. In general, helicopter operators cannot be as readily identified with an area of operations due to less stringent licencing limits pertaining to operating rights and to the charter nature of this part of the industry. The companies listed in this study have had operations of some kind in the Arctic within the last five years. They are therefore familiar with conditions and limitations of the work environment.

2.2.2 Private Companies

Table 6 lists the corporations which are operating aircraft on a private basis in the Arctic either as owners or leasors. These aircraft are all under Private Register and would not therefore be normally disposable under CTC regulations except for operations carried out by the Company concerned.

2.3 OPERATIONAL AIRSTRIPS

A total of 89 airstrips have been identified which are of importance in the event of an oil spill cleanup operation. Of these, four are inland and would be used as supply bases only. The size and sophistication of the facilities varies from negligible in the abandoned sites to full in the larger centres. Table 7 summarizes operational characteristics of the various airports. In this section, the regions defined in the Introduction will be used to summarize the location. There are two main parameters which define the value of an airstrip; location and function.

The airport function is defined by the following classification:

- Major Community The airstrip serves a major community which also often acts as a distribution centre for a
 particular area. The facilities are generally of a high quality including longer than average runways and better
 than average navigational equipment. There is normally a significant number of regularly scheduled flights and
 most services are available.
- Work Site The airstrip serves a mine, oil or gas exploration site which is not also a native settlement. The
 operator is usually a private corporation and the facilities are often of a temporary nature.
- Minor Community The airport serves a minor community which is not served by a regularly scheduled carrier
 on a frequent basis. The runways are usually shorter than average and flight approach instrumentation is
 minimal.
- Weather Station An airstrip established by the Department of Transport primarily to serve a weather station.
- Military (Active) The airstrip is used by the United States Air Force or Canadian Armed Forces for military
 purposes (as DEW Line site or Coast Guard Station, for example). The strip is operational and manned year
 round.
- Abandoned These are sites which have operational status on an emergency basis for V.F.R. only. These sites
 have runways and shelter is often available in abandoned buildings.

Table 8 summarizes the sites according to these two classification parameters (location and function).

A total of 85 airstrips have been identified as being of operational value. Of these, 25 are in the Western Arctic, 10 are in the Eastern Arctic, 19 are in the High Arctic, 29 are in Hudson Bay/Ungava/Foxe Basin and 2 are on the Labrador Coast.

A recent press release by the Ministry of Transport indicated that four airports in Labrador will be significantly upgraded and improved this year. The airports are at Nain, Rigolet, Cartwright and Makkovik. The availability of these airports will greatly improve the operational capability to combat an oil spill in the region of the Labrador coast.

There are a total of 15 major community airstrips, 16 work sites, 30 minor community sites, 3 weather stations, 15 active military sites and 6 abandoned sites. The number of major and minor community airstrips will not change very suddenly, but the work sites can be abandoned on short notice and their operational status could be questionable at any given time.

2.5 UPDATING

Airstrips

The airstrip data are extremely vulnerable to change. New airstrips are being constructed and others abandoned on a week to week basis, closely following the level of exploration and drilling activity. In the context of a possible oil spill, sources for the most up-to-date information are vital.

The best source for current airstrip data would be Pacific Western Airlines, Hercules Operations Division, Edmonton, Alberta. Phone 403-455-4101. They offer a subscription service for Arctic airstrip data at a cost of \$250 per month.

Secondary sources include locally based air services in the appropriate area, oil companies and various Government Departments such as the Canadian Armed Forces, Royal Canadian Mounted Police and the Land Use Agencies.

Air Carriers

Changes in Companies and their bases of operation are relatively stable and can be verified by contacting the sources listed above.

Aircraft

Significant changes or advancements in the type of aircraft and helicopters available are relatively infrequent and can be determined by reference to the latest Canadian Aviation Directory.

2.6 SPECIAL TECHNOLOGY AND FUTURE DEVELOPMENTS

ParaDrop

Significant advances have been made in recent years in the accuracy and reliability of this method of cargo delivery. The Canadian Armed Forces advise that they can handle a single unit drop of 35,000 lbs., using a C130 Hercules with suitable packaging. A case of eggs can be delivered without breakage. This system would be very effective for a fast response in an oil spill situation on land or sea ice, and possibly even for containment systems in the case of a sea spill.

Lapes - Low Altitude Parachute Extraction System

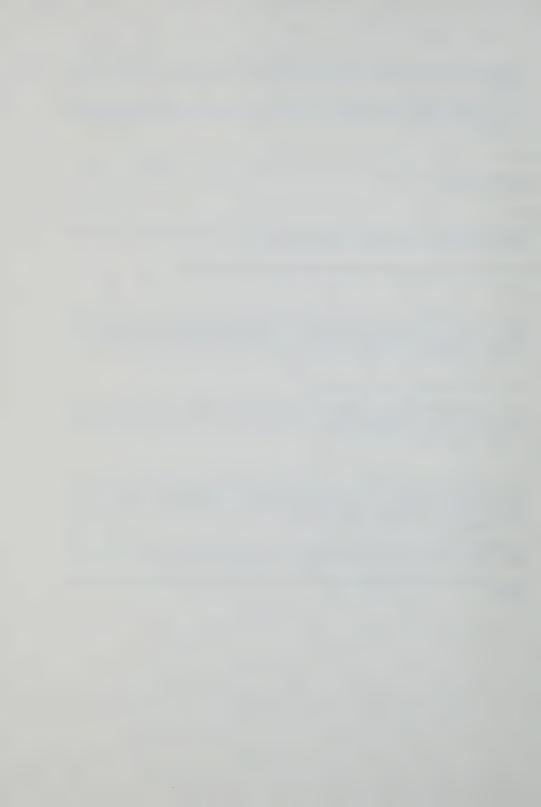

Cargo may be delivered with pinpoint accuracy by this technique. It involves an aircraft such as a C130 Hercules with a rear cargo ramp, flying at about 10 feet over the drop zone (which must be fairly smooth) and deploying a parachute to extract the load. Military hardware such as tanks, ammunition and fuel drums have been delivered by this method, although with significant spoilage.

Future

Only minor advances are to be expected in the size and cargo capability of transport aircraft and helicopters. These advances will probably be in the military inventory initially. The DeHavilland Dash 7 Medium Transport (10,000 lbs. payload), with good STOL performance, will enter service next year. It may be available in an Arctic Carrier's fleet (Wardair). Unfortunately it does not feature a rear cargo door and suffers a handicap for loading large packages, and ease of loading/unloading.

Navigational aids are improving steadily, with many aircraft from Twin Otters up being equipped with on-board very low frequency area navigation systems. Introduction of the Navstar Satellite Navigation System in the early 1980's should have a major impact on Arctic navigation and bad weather landing capability.

Air Canada's recent takeover bid for Nordair could have an impact on the equipment available and quantity of service.

3.0 SUMMARY OF MARINE SYSTEM

3.1 AVAILABLE VESSELS

Vessels that have been involved in arctic re-supply at any time since 1970 are listed in Table 9. Table 10 gives the operational characteristics of the vessels which have been included in this survey. Some vessels listed in Table 9 do not appear in Table 10, because they have been taken out of service, are unstrengthened or are otherwise not available for future work in the Arctic.

The displacement is the weight of water which a vessel displaces when fully loaded, an important consideration when ice breaking potential is required. The deadweight is a measurement of a ship's tonnage which indicates the carrying capacity of a ship in tons weight*.

The draft is the distance from the water line to the lowest point on the keel for a laden ship in calm water. The largest hatch dimension reflects the size of package which might be accepted as well as the possibility of landing aircraft upon the deck.

There are two systems of classifying ships according to their capability in ice; Lloyds Registry and the Canadian Ice Classification. Lloyds system varies from 1* as a strengthened merchant to the less strengthened 2, 3 and 4 classes. An unstrengthened vessel is not classed. The equivalents to these ratings in the Canadian Ice Classification are A, B, C. D and E.

This system also classes icebreakers according to the number of feet of ice through which they can proceed at a constant rate.

No attempt has been made to include those vessels trading into the Port of Churchill for the following reasons: These voyages are made on a 'one off' basis (i.e. a voyage charter) and are not, except in rare cases, repeated. Further, the vessels employed in this trade are not strengthened for navigation on ice.

3.2 GOVERNMENT AGENCIES AND COMPANIES OPERATING IN THE NORTH

The government agencies that are closely associated with shipping in the Canadian Arctic are identified in Table 11. The shipping companies are identified by the type of vessel they operate.

3.3 PORTS AND ANCHORAGES

On Table 12 the ports and anchorages have been discussed under the same five regional headings as identified in the Introduction to this report. The ports have been divided into five categories and an evaluation of the quality of shelter offered and anchorage is provided.

3.3.1 Categories of Ports and Anchorages

The following five categories have been adopted:

- Major Settlements Those which serve, among other things, as redistribution ports for smaller settlements and commercial developments. An example is Resolute Bay.
- Minor Settlements Those which are traditionally re-supplied each summer by sealift, e.g. Pond Inlet.
- Commercial Sites Serving those commercial activities engaged in mining or the search for oil and gas, e.g. Rea Point or Nanisivik.

Abandoned Settlements

Anchorages

^{*}Tonnage is in terms of the metric ton of 2,205 lbs. or 1,000 kilograms. Slight errors may occur since many original registrations were in Avoirdupois tons (2,240 lbs) which is 1.6% heavier.

(2) Based on an unstrengthened vessel.

(1) Based on an icebreaker (Arctic Class 3).

3.3.2 Selected Sites

Altogether 87 ports and anchorages have been identified. In general, all of them are considered capable of providing the needed measure of shelter and/or support.

3.3.3 Pollution Control Zone

The number indicated refers to a zone in the Arctic designated by the Arctic Shipping Pollution Prevention Regulations, a publication of the *Ministry of Transport* acting for the Government of Canada. This restricts the various classes of ships to specific operating dates corresponding to the expected ice conditions and depending on the vessel's ice classification.

3.3.4 Chart Number

The chart number listed indicates the Canadian Hydrographic Service reference number for marine charts.

3.3.5 Degree of Shelter

The degree of shelter was determined by judgement and was based upon the direction and strength of winds, the tidal range and currents, ice movement and surrounding land configuration.

3.3.6 Anchorage

The anchorage was appraised using judgement and considering the quality of the sea bottom, the depth of anchorage and its distance from the beach, the tidal range and the swinging room available to vessels at anchor.

3.4 SOURCES AND CONTACTS

The following sources were utilized in collecting data on the marine system portion of this study. Personal knowledge of Capt. T.C. Pullen has been a primary source of much of the data.

Lloyds Register of Ships for 1967-68, 1976-77, 1977-78.

List of Shipping 1976-77.

Lloyds List of Shipowners 1976-77.

Ministry of Transport After-Action Reports: PACER DEW, PACER PINE & PACER BASIN 1970-1977.

Ministry of Transport After-Action Reports: Hudson Bay & Frobisher Bay Sea-lifts 1971-1977.

Ministry of Transport After-Action Reports: Resolute Bay Sea-lifts 1970-1977.

Pilot of Arctic Canada:

Volume I - General

Volume II — Eastern Arctic

Volume III - Western Arctic

Labrador & Hudson Bay Pilot

Radio Aids to Marine Navigation (Atlantic & Great Lakes)

Radio Aids to Marine Navigation (Pacific Region)

Climate of the Canadian Arctic, Marine Sciences Branch, Department of Environment 1970.

Arctic Shipping Pollution Prevention Regulations.

Symbols and Abbreviations used on Canadian Charts 1976.

Charts issued by the Canadian Hydrographic Service as shown on Tables 12A to 12E.

3.5 UPDATING

With the passage of time ships shown on Tables 10 and 11 will, on account of age, sale or transfer, no longer be employed in northern waters and will be replaced by others. For instance, Salen of Stockholm which at present has a contract to ship lead/zinc concentrates from Strathcona Sound to Antwerp in its own vessels (Gothic Wasa, Baltic

Wasa, etc.) for a period of 3 years will eventually be replaced by a new Canadian icebreaking bulk carrier, the M/V Arctic. Such deletions from and additions to the arctic shipping scene must be reflected in the listings.

Similarly, listings should show changes in the Coast Guard icebreaker fleet, either when new construction appears on the scene (e.g. the 2 new 'R' class icebreakers being built on the west coast) or when temporary changes occur (e.g. when existing ships are taken in hand for long refits).

3.6. SPECIAL TECHNOLOGY AND FUTURE DEVELOPMENTS

3.6.1 New Mines

Arvik, Cominco's lead/zinc deposit on Little Cornwallis Island is awaiting development when world prices for those minerals recover from their present depressed state. At that time, of course, berthing facilities matching those serving Nanisivik on Strathcona Sound will be constructed. Shipment of the year's production, about 200,000 tons of concentrates will be accomplished during the summer navigation season by suitably strengthened bulk carriers.

When the iron ore body at Mary River on North Baffin is developed the product will be shipped to Europe on a yearround basis in a fleet of icebreaking ore carriers displacing at least 200,000 tons. Production at the outset would be 2 million tons of direct shipping ore rising after a year or so to 4 million tons. Port facilities would likely be established at the bottom of Milne Inlet where there is good shelter and water.

3.6.2 Oil

While oil has not yet been found in the high arctic in commercial quantities, the on-going effort to find it continues and the likelihood must be that a significant find will ultimately be made. If and when this occurs, delivery to southern markets will likely be by icebreaking tankers built for the purpose. This too would be a year-round operation by vessels displacing 200,000 tons.

3.6.3. The Polar Gas Project

The Polar Gas Project presented (in Dec. 1977) a submission to the National Energy Board (NEB), and through it to the Government, for approval to proceed with its plan to build a pipeline from the Arctic islands southward along the Boothia Peninsula and the west coast of Hudson Bay to southern markets. In all, it represents a 3,500 mile undertaking which will have an enormous impact on ships and shipping over a period of at least 5 years. The intention is to transport 1½ million tons of cargo into Hudson Strait and a wide variety of destinations in the high arctic. The closest project to rival the magnitude of the Polar Gas Project was the construction of the Distant Early Warning (DEW) Line 20 years ago.

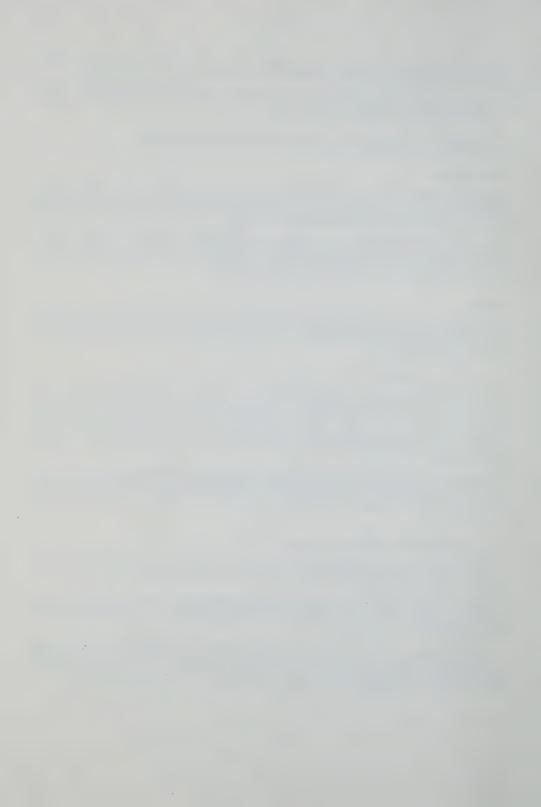

Once the construction phase has been completed there will be an on-going commitment to re-supply all the sites annually. To accomplish this will call for the services of 2 or 3 extremely powerful servicing vessels built to high icebreaking standards. In addition, of course, a number of ships, probably chartered and likely unstrengthened, would bring cargo into selected redistribution ports for stockpiling and onward delivery by the icebreaking vessels above.

3.6.4. Liquid Natural Gas (LNG) by the Marine Mode

A strong competitor in the arctic transportation field with the Polar Gas Project is the Arctic Petro Carriers group which is planning to liquefy arctic island gas at Bridport Inlet on Melville Island and ship it to an eastern Canadian port by means of icebreaking ships.

Sufficient reserves of gas have already been established to justify such a marine mode whereas very much more will have to be proven before the all-pipeline project can be seriously considered as an alternative. Arctic Class 7 LNG icebreakers would be employed displacing about 150,000 tons and operating year-round delivery between 12 and 14 shiploads yearly.

It should be noted that the liquefaction plant, and many other facilities would be constructed in the south and then be moved north on barges which would be joined together and placed in a suitable sheltered refuge. Such a 'modular' approach will be used for all large projects and will have a heavy impact on the arctic marine scene calling for special towing/pushing operations to ensure delivery at site with accompanying icebreaker escort.

3.6.5 The Beaufort Sea

Dome Petroleum is at present pushing a proposal to build or acquire an Arctic Class 10 icebreaker (the ultimate icebreaker) and has suggested that Government underwrite a share of the cost. Whatever happens, and should that vessel be built, the icebreaking capability that would become available in the Beaufort Sea, in support of the offshore drilling program there, would not only ensure the safety of the drill-ships but could extend the season by a substantial amount.

3.6.6. Miscellany

In 1974 an ice-strengthened (Type 'B' — Arctic Shipping Pollution Prevention Regulations) vessel designed especially for the role, carried 95 tourists into the high arctic penetrating Kane Basin (80 degrees north latitude) and as far west as Barrow Strait (beyond Resolute Bay). This was the first serious attempt to introduce tourists by sea to that region and was an unqualified success.

Flowing from this it has now been learned that the sponsors and operators of the ship are planning two more cruises, this time through the Northwest Passage entering from the west. They would take place in 1979 if the necessary approvals and clearances can be obtained.

During 1977 another first was established when two private yachts attempted, and succeeded, in 'sailing' through the Northwest Passage. One was Dutch and the other Canadian. There will be others in the future. Such endeavours are risky, achieve little of significance and represent a charge on the taxpayers because the Coast Guard must monitor the progress of such vessels in the event they become beset and threatened.

4.0 SUMMARY OF LAND SYSTEMS

The land system is not a significant consideration in supply to the north in comparison with the air or marine modes

4.1 RAIL ACCESS TO THE NORTH

Rail access does not penetrate north of Hay River in the Northwest Territories or Whitehorse in the Yukon Territory. Rail does reach Churchill on Hudson Bay and Moosonee on James Bay and can be used to ship goods to Churchill Falls in Labrador.

All of these lines are connected to the southern systems directly by a standard gauge (4 ft. 8 %) track except the White Pass and Yukon Route which has a No. 3 gauge track (3 -0") to Skagway and a ferry connection to Vancouver. The equipment on these lines is capable of accommodating passengers and substantial volumes of heavy material.

Each of these railways has sufficient storage area and off-loading facilities at their northern points to act as a mode transfer point in the supply line to the northern support bases in the event of an oil spill. Freight is carried by barge from Hay River to the Beaufort Sea via the Mackenzie River or by ship to the Hudson Ungava Bay area from Churchill or Moosonee. No easy connection can be made to the Labrador Coast but a trail does exist to Goose Bay and could be sufficiently upgraded in the future.

4.2 ROAD ACCESS TO THE NORTH

4.2.1 All Weather Roads

Direct road access to the Northwest Territories and the Yukon Territory is possible year-round within a 3,600 mile network of roads.

Edmonton, Alberta is the main southern city connected to Hay River and Yellowknife in the Northwest Territories and as far north as Dawson City and Whitehorse in the Yukon.

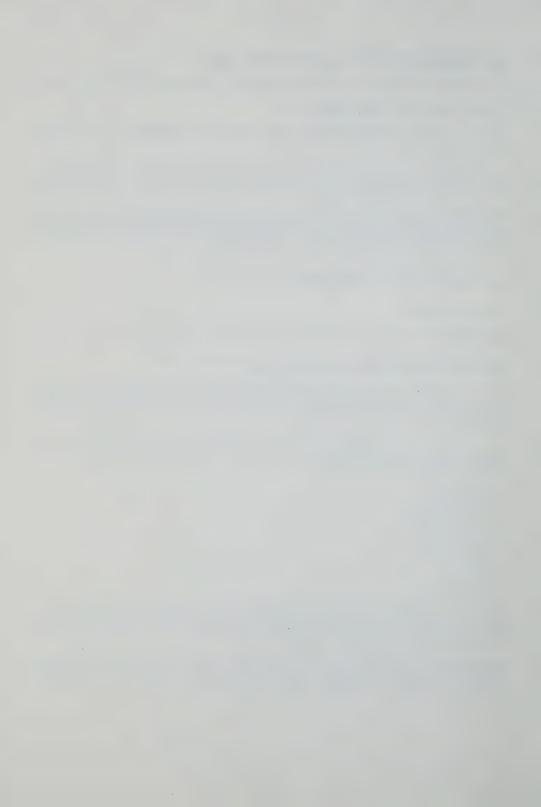

The system is primarily a gravel surfaced network with an approximate width of 24 feet and design speed of 80 KPH (50 MPH). Bridges are numerous and are generally of timber construction capable of carrying loads within the territorial restrictions under a 15 KPH speed limit. These restrictions can be exceeded through the purchase of a permit from the respective territory and use of specially designed trailers and pilot cars to the resident engineer's satisfaction.

There are various trucking companies out of Whitehorse, Yukon, Edmonton and Peace River, Alberta that run regularly scheduled or contracted services to communities on these all-weather roads. Communities with regular service are as follows:

Hay River, N.W.T.
Pine Point, N.W.T.
Fort Smith, N.W.T.
Fort Resolution, N.W.T.
Fort Providence, N.W.T.
Rae/Edzo, N.W.T.
Yellowknife, N.W.T.
Fort Simpson, N.W.T.
Whitehorse, Y.T.
Mayo, Y.T.
Dawson City, Y.T.
Beaver Creek, Y.T.

It should be noted that there is at present an all-weather road between Inuvik and Fort McPherson but since it is not yet connected to the network, permanent road access to the Arctic coast cannot be considered as a supply line to northern communities. At best, roads could be used to supply arctic communities through Hay River via barge along the Mackenzie River or Yellowknife and Whitehorse via airfreight.

In the eastern portion of the Canadian north, road access to the coast is limited to Fort George, Quebec, and Happy Valley 'Goose Bay, Labrador. The paved road to Fort George is feasible as a direct supply line to northern communities. To the Labrador coast however, supplies must be transported by rail to Esker, Labrador and then by a gravel track through private land to the port of Happy Valley/Goose Bay.

4.2.2 Ferries

Large river crossings are frequently serviced by car ferry in the north due to the high construction cost of a bridge. Currently there are five ferries in operation and their characteristics are listed in Table 13. These ferries cannot operate all year round and ice bridges are constructed in the winter months. This solution, however, still leaves 60—90 days per year during freeze-up and break-up periods when traffic is unable to cross.

TABLE 13 FERRY DATA

Community	River	Type of Ferry	Capacity (Tons)	Ferry Season	Ice Bridge Season
Fort Providence	MacKenzie	Car Ferry	100	June 1- Nov 15	Dec 15- Apr 15
Ford Simpson	Liard	Car Ferry	65	May 15- Nov 1	Dec 1- Apr 15
Ross River	Pelly	Cabled Barge	N/K	Summer on Demand	Nil
Dawson City	Yukon	Car Ferry	65	May 15- Oct 15	N/K
Arctic Red River	MacKenzie	Car Ferry	20	N/K	N/K

N/K - not known

4.2.3 Winter Roads

During the winter months, roads are built of snow and ice as temporary access roads to small communities normally serviced only by air. There are literally thousands of miles of these roads throughout Northern Canada but they are of little concern due to their local function of stockpiling supplies.

A major winter road has been constructed in the past along the Mackenzie Valley from Fort Simpson to Inuvik. Demand for such a road is very low and has not justified opening it up every year on a regular and reliable basis although it is being constructed in 1978.

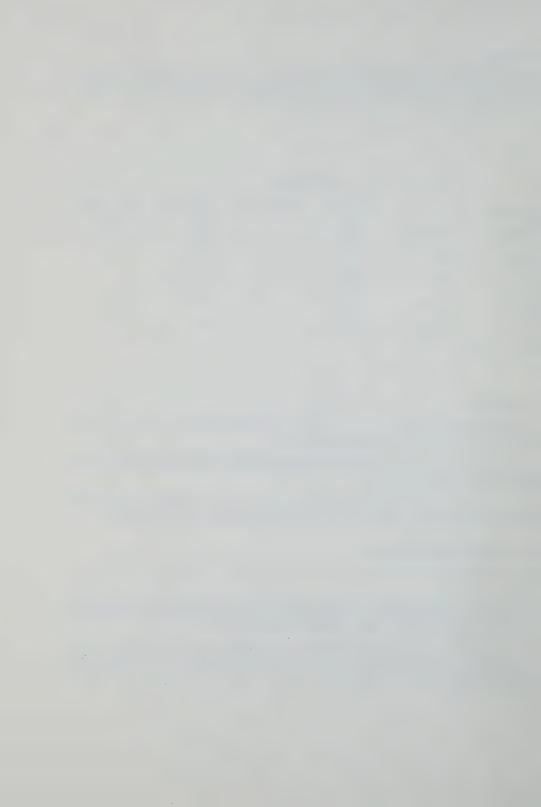

There are two of these roads of importance in the MacKenzie River Delta area. One is a 65 mile access road to Aklavik and the other is a 120 mile road to the settlement of Tuktoyaktuk from Inuvik. Both are maintained on a regular basis out of Inuvik and provide winter access from a major settlement to an air and marine port respectively.

4.3 AIR CUSHION VEHICLES

Air cushion vehicles (ACVs) are capable of carrying loads over water, ice and terrain inaccessible to other forms of surface transport.

The Northern Transportation Company was the first to employ ACV's in the arctic as supply vessels to nearby offshore drilling rigs, in the Beaufort Sea. Centred in Inuvik, these vessels operated satisfactorily year-round in all types of weather. However, as the drilling rigs moved farther off-shore in search of oil, the distances involved were beyond the ACV operating range. As a result, these vessels have been taken out of service.

The only ACV at present in operation in the Canadian north is at Tompkins Landing in Northern Alberta. It is a pilot project in the use of hovercraft for ferries across large river crossings. A 66 foot vessel is used to transport vehicles across the Peace River on a winched cable system. Although operational difficulties are being encountered, the service rendered by this vessel is considered good since the freeze-up and break-up shut downs of the conventional ferry are eliminated.

4.4 SOURCES AND CONTACTS

The collection of data on land systems has utilized various sources within the public and private sector. These contacts are listed below in flour groups; rail, road, truck and air cushion vehicle transport.

4.4.1 Rail Contacts

Mr. Jack H. Wood Traffic Manager White Pass and Yukon Route 701 West George Street Vancouver, B.C. V7Y 1E6 Tel. (604) 683~7221

Transport Canada; Bell Voyageur 002 ACV — Cold Weather Evaluation; August 1974.

Transport Canada; Bell Voyageur 002 ACV — Engineering and Commercial Evaluation; June 1975.

4.5 UPDATING

An accurate record of all new land transportation links opening up areas of the north or major reconstruction projects upgrading the quality or structural capacity of the links should be noted so that land-based support lines to the southern centres can be fully utilized.

4.6 FUTURE DEVELOPMENTS

Two major developments in the land network should be completed by 1980. Both are within the highway sector and involve major implications to multi-modal transit of freight and people to the north.

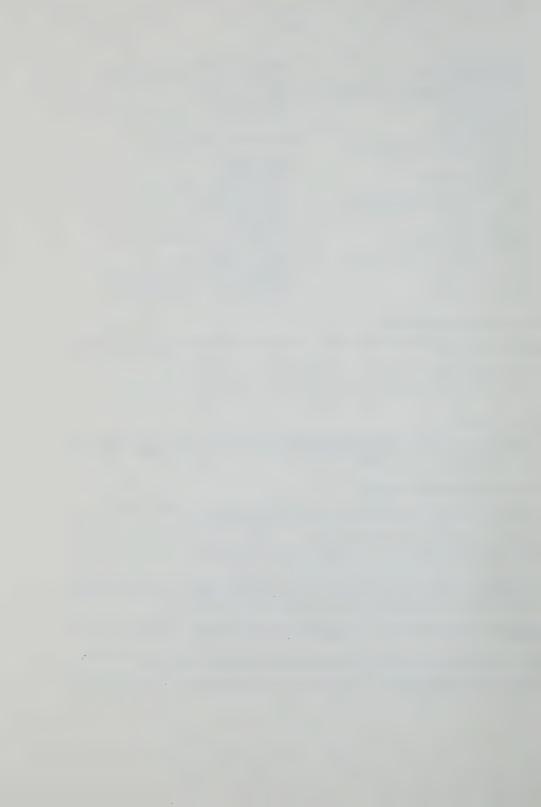

A road link from Carcross, Yukon to Skagway, Alaska is now under construction and will provide a direct link from Whitehorse, the capital city and major distribution centre for the Yukon, to a major port. This will complement the railway service now in operation and provide a better service with more flexibility.

Another road link currently under construction is the final stage of the Dempster Highway. It will connect the present all-weather road servicing Dawson City to Inuvik, thereby providing year-round land access to a major air distribution centre within the Arctic Circle. A further extension of this road to the port of Tuktoyaktuk is in the design stages and will be the first permanent land access to the Canadian Arctic coastline.

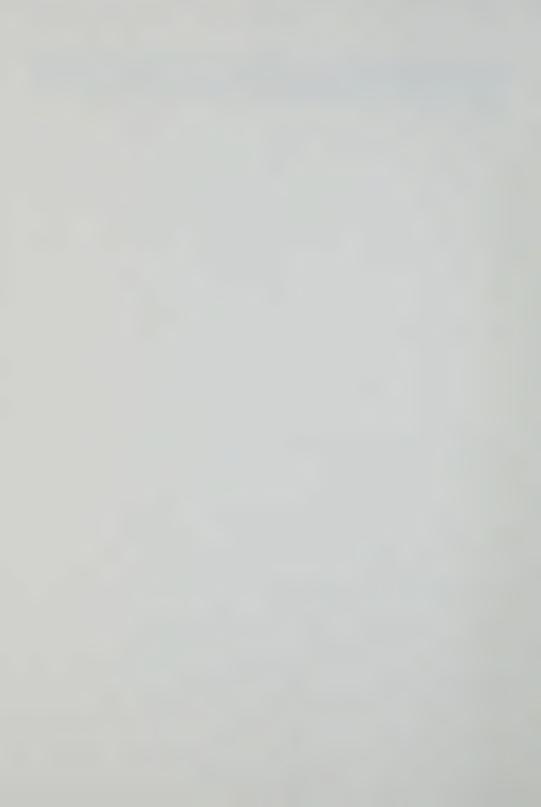

Societe de Developpement de la Baie James is at present studying the feasibility of three new links from the Matagami-Fort George road; to Fort Rupert, Eastmain and Nouveau Comptoir, all on James Bay.

Newfoundland is also planning a permanent link from Labrador City to Churchill Falls over a new alignment. There is an existing gravel track to Happy Valley/Goose Bay which could make coastal access possible.

The Motor Truck Jan/78 issue describes a proposal for a cable bridge across the Mackenzie River at Fort Providence. No official status can be attached to this proposal.

The Canadian Coast Guard is investigating some very promising future uses of air cushion vehicles in the Canadian north. Tests on the Bell Voyageur ACV in the MacKenzie Delta have proved the vessel's adaptibility to cold climates and capability of traversing almost all types of topography. Along with its obvious potential as a supply vessel to operational bases during an oil spill countermeasure program, it has also been tested with success as a moving platform from which oil dispersants can be sprayed.

5.0 SUMMARY OF COMMUNITIES

The communities in the north are important as bases of supply and operation during any oil spill cleanup program. An evaluation of the equipment and manpower is a vital requirement in the development of contingency plans

5.1 COMMUNITIES IN THE NORTH

A total of 90 sites has been identified in the review of community resources. The support facility characteristics of the various centres are detailed on Table 14. The table is broken into five parts corresponding to the five regions described in Chapter 1 as follows:

Table 14A	Western Arctic	25	communities
Table 14B	Eastern Arctic	12	communities
Table 14C	High Arctic	7	communities
Table 14D	Hudson Bay/Ungava/Foxe Basin	30	communities
Table 14E	Labrador Coast	_16_	communities
	TOTAL	90	communities

It is interesting to note that JP2 is an all purpose fuel used for heating and for aircraft.

It is important to know the capabilities within the communities to provide two types of equipment; water transport vessels and construction equipment. Tables 15A, 15B, 15C, 15D and 15E give the water transport vessel characteristics by region. All vessels longer than 20° are listed. These vessels would be used to off-load supply ships and provide operational support for any oil spill cleanup. These tables clearly show that few of the communities will be able to make significant contribution in this manner.

Tables 16A, 16B, 16C, 16D and 16E list the available construction equipment by region. Some equipment is available in most communities but the quantities are limited. Grading equipment is generally available at all airports.

5.2 SOURCES AND CONTACTS

The collection of data on community resources has utilized a number of sources. These sources are identified below by three major geographic areas, the Northwest Territories, Quebec and Labrador.

5.2.1 Northwest Territories

The prime data source utilized for communities in the Northwest Territories was a questionnaire sent to all the study communities. These questionnaires were sent, wherever possible, to specific individuals with whom members of the study team were familiar. When this was not possible the recipient was the Settlement Manager or his equivalent.

Data on many communities, along with airport data were obtained from Canadian Forces Northern Region Headquarters in Yellowknife. The contact was Captain C. Jordaan.

Data on DEW Line sites were obtained from the National Defence Headquarters in Ottawa. The contact for this information was Major R. Paukstaitis, Domestic Operations Section, Continental Plans Coordinator.

Considerable data were obtained from the 1977 Canada North Almanac, produced by the Research Institute of Northern Canada, Yellowknife.

Data on some communities were supplied by F. F. Slaney and Co. Ltd. in Vancouver who are involved in a similar study. The contact is Doris M. Morris. Fenco Consultants, of Calgary, who are also working on this study, providing data pertaining to some communities as well.

Information on individual sites was obtained from persons specifically contacted for that purpose. For example; data on Rea Point were kindly provided by L. J. Franklin, Vice-President, Operations, for Panarctic Oils Ltd.; data on Nanisivik were obtained from Mr. James of Strathcona Mineral Services Ltd. in Toronto.

Mr. G. W. Elliott, Manager, Designated Airports, Transport Canada (Winnipeg Office), was most helpful in providing extensive data for all communities where Transport Canada has a presence.

5.2.2. Quebec

Data on some communities in Quebec were obtained from the Canadian Transport Commission report on Isolated Communities, Digest of Transportation, Social and Economic Data (June 1977).

A considerable amount of data on northern Quebec communities was provided to us, through our Montreal office, by Mr. Eric Val of the Northern Quebec Inuit Association. Further data were provided by the Direction Générale du Nouveau-Québec (M. André Huot) and the Department of Indian and Northern Affairs (M. Claude Philippe) and, for information on Deception Bay, Mr. Dickson of Asbestos Corporation.

5.2.3. Labrador

Questionnaires were sent out to those Labrador communities within our study area. Further information about these communities was provided by Mr. A. Pike and Mr. A. Flynn, both with Labrador Services, Department of Rehabilitation and Recreation, to our St. John's office. Data on Churchill Falls were provided by Mr. A. Grant and Mr. S. Lewis, both with the Churchill Falls (Labrador) Corporation Limited.

5.3 UPDATING

The updating of data on a particular community can not be accurately completed without direct contact to the local authority. Contacts are provided on the Appendix sheets.

5.4 FUTURE DEVELOPMENTS

With increased exploration in the Canadian Arctic it is feasible that new communities could be established within a relatively short time period. This type of community must have good transportation facilities either by air and/or sea. Therefore, these locations are most likely to be suitable sites for operational bases and should be added to the resource inventory.

The requirements for a site to be considered suitable as an operations base may possibly change with changes in the use of various aircraft and ship type. For this reason future developments of a technological nature may make more of the existing settlements suitable as operational bases.
